In a typical computer, a microprocessor, such as Intel's 80C286 or 80386 processor, operates under the control of the central processing unit, such as Intel's 80C800 chip, which implements the instructions to the processor. A typical microprocessor contains an arithmetic logic unit, a barrel shifter, an address generation unit, an instruction register, a decoder, a processor status unit, and a data cache. Some of these components may be shared by processors from different manufacturers. The arithmetic logic unit performs arithmetic functions, while the barrel shifter and address generation unit perform logical functions. The arithmetic logic unit includes two types of functional units, one including adders, registers, and one-bit shifters, and the other including registers and arithmetically intensive shifters. The barrel shifter includes arithmetic, control, and data buses and is arranged to perform one or both of left and right shift operations, a bitwise logical or, arithmetic logical operations, and logical vector operations. Some such arithmetic or logical operations are described in U.S. Pat. Nos. 4,882,964 and 4,723,115, issued to G. G. Stolarczyk. Both arithmetic and logical operations typically involve three clock phases, three or more registers, and multiplexers.
